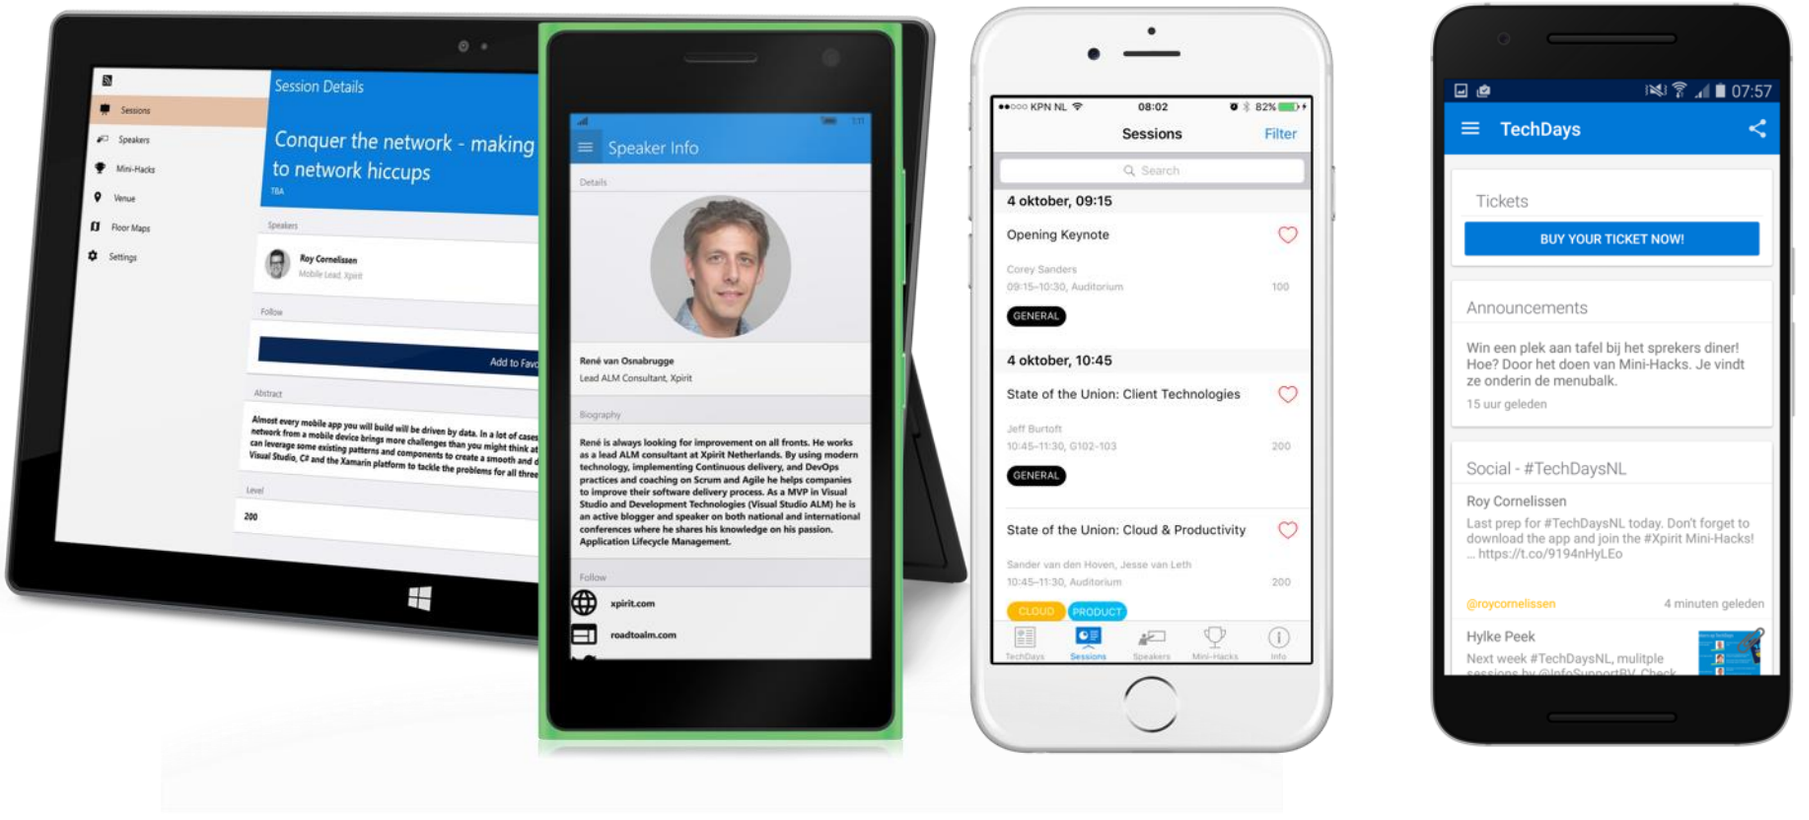
Xamarin.Forms

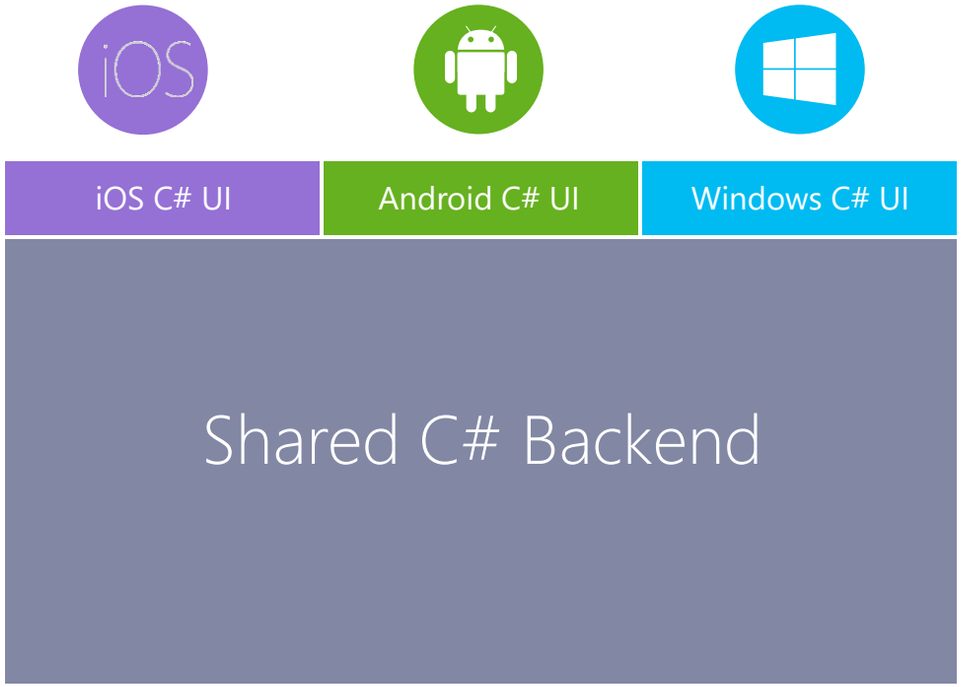
Xamarin hands-on-labs

Meet Xamarin.Forms

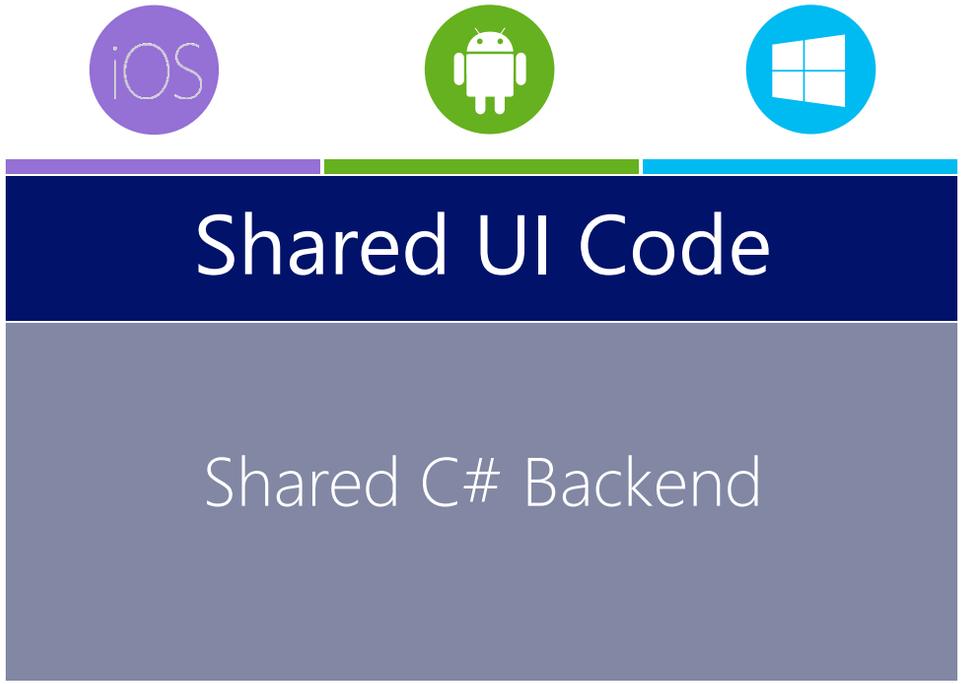


Build native UIs for iOS, Android, and Windows from a single, shared C# codebase.

Xamarin + Xamarin.Forms

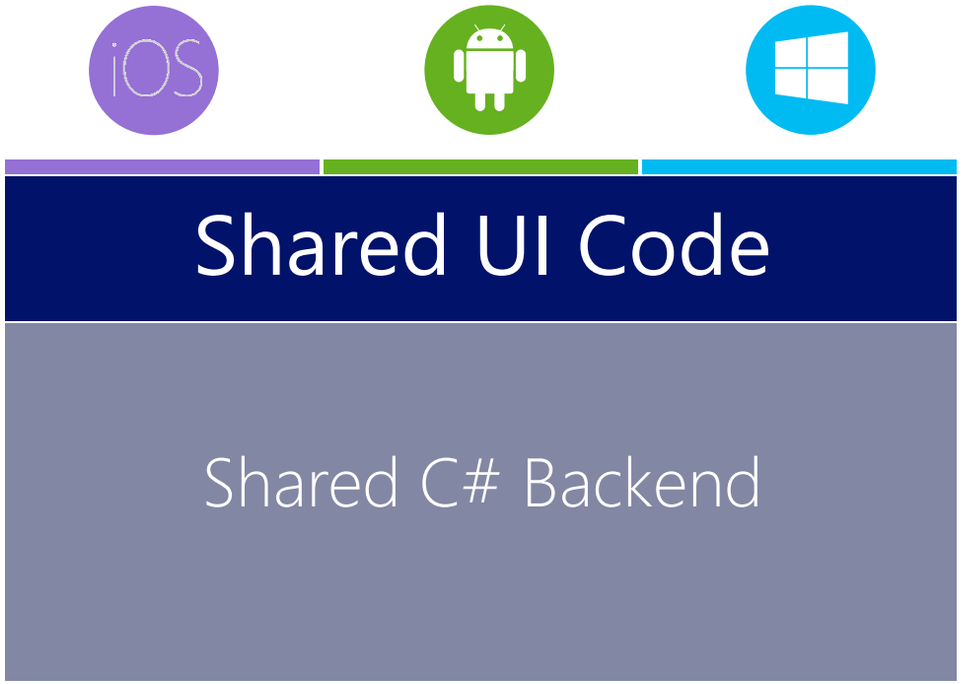


Traditional Xamarin Approach



With Xamarin.Forms:
More code-sharing, all native

What's included



- ✓ 40+ Pages, layouts, and controls
  (Build from code behind or XAML)
- ✓ Two-way data binding
- ✓ Navigation
- ✓ Animation API
- ✓ Dependency Service
- ✓ Messaging Center

Community

- Public Roadmap: aka.ms/xfroadmap
- 70 contributors
- 700 merged pull requests
- 37 evolution proposals

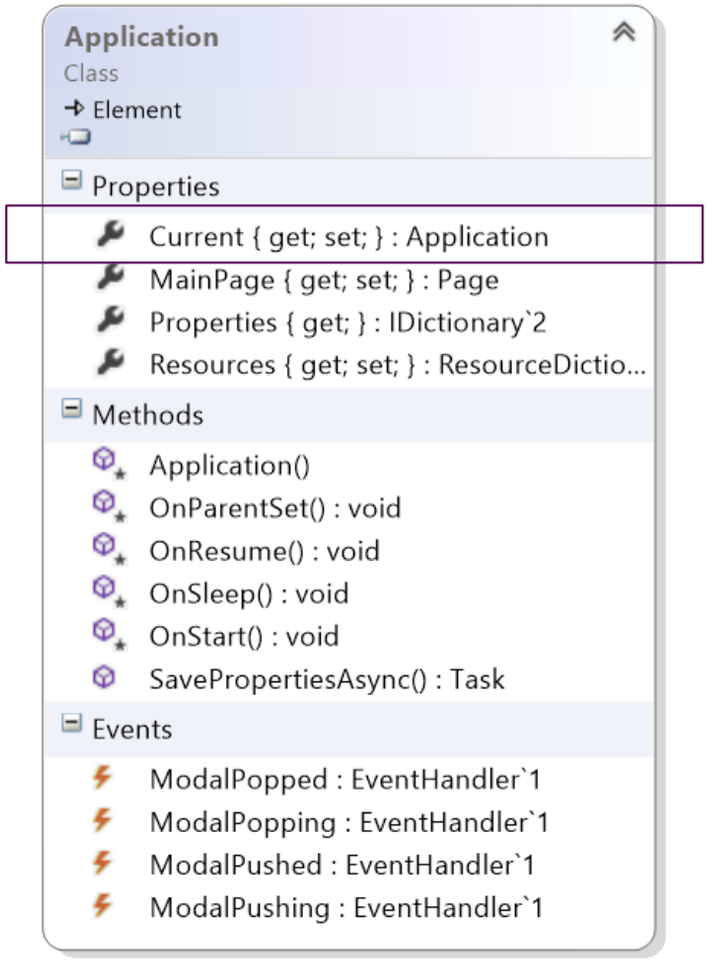
                      StringFormat='R={0:X2}'}" />
```

Xamarin.Forms app anatomy

- Xamarin.Forms applications have two required components which are provided by the template

Xamarin.Forms Application

- `Application` class provides a *singleton* which manages:
  - Lifecycle methods
  - Modal navigation notifications
  - Currently displayed page
  - Application state persistence
- New projects will have a derived implementation named `App`



Note: Windows apps *also* have an `Application` class, make sure not to confuse

Xamarin.Forms Application

- `Application` class provides lifecycle methods which can be used to manage persistence and refresh your data

```
public class App : Application
{
    // Handle when your app starts
    protected override void OnStart() {}
    // Handle when your app sleeps
    protected override void OnSleep() {}
    // Handle when your app resumes
    protected override void OnResume() {}
}
```

Use `OnStart` to initialize and/or reload your app's data

Xamarin.Forms Application

- `Application` class provides lifecycle methods which can be used to manage persistence and refresh your data

```
public class App : Application
{
    // Handle when your app starts
    protected override void OnStart() {}
    // Handle when your app sleeps
    protected override void OnSleep() {}
    // Handle when your app resumes
    protected override void OnResume() {}
}
```

Use `OnSleep` to save changes or persist information the user is working on

Xamarin.Forms Application

- `Application` class provides lifecycle methods which can be used to manage persistence and refresh your data

```
public class App : Application
{
    // Handle when your app starts
    protected override void OnStart() {}
    // Handle when your app sleeps
    protected override void OnSleep() {}
    // Handle when your app resumes
    protected override void OnResume() {}
}
```

Use `OnResume` to refresh your displayed data

Persisting information

- `Application` class also includes a `string` >> `object` property bag which is persisted between app launches

```
// Save off username in global property bag
Application.Current.Properties["username"] = username.Text;
```

```
// Restore the username before it is displayed
if (Application.Current.Properties.ContainsKey("username")) {
    var uname = Application.Current.Properties["username"] as string
                    ?? "";
    username.Text = uname;
}
```

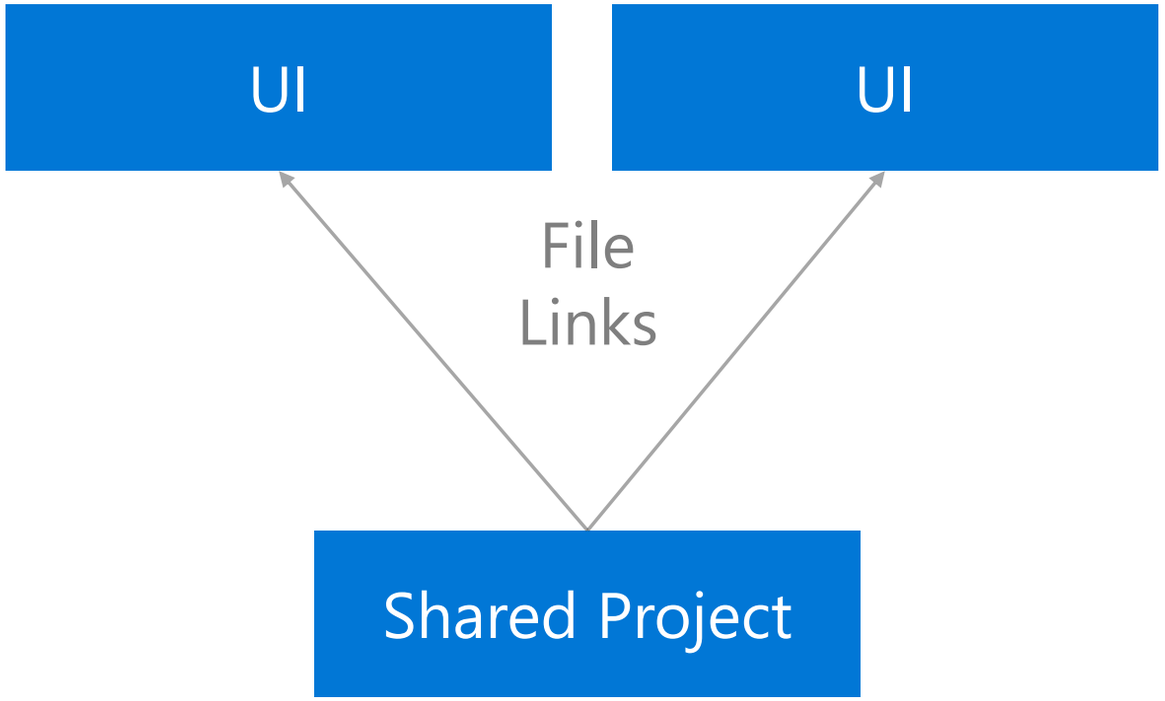
Shared Project



Compile time concept

Files are **compiled into** target platform binary

Shared Project

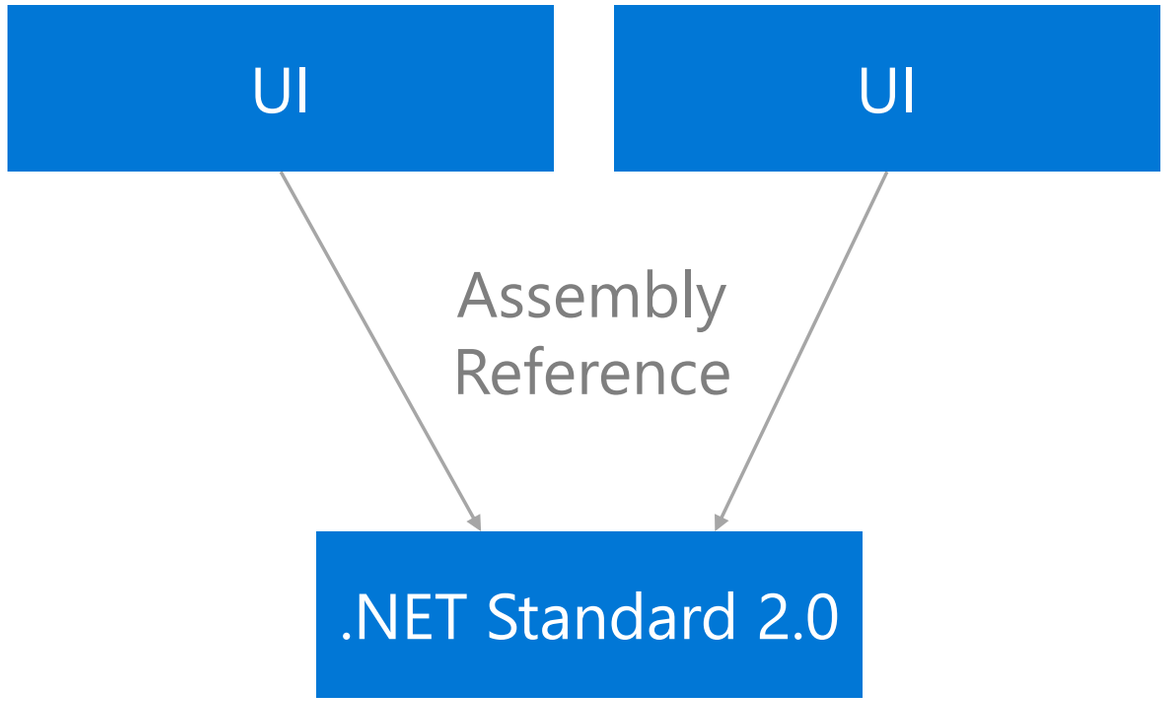
Pros

- One code library project
- Code is reused
- Can use compiler directives
- Platform-specific code easy

Cons

- No assembly to reuse
- Uses less known file linking
- Testing potentially harder

.NET Standard 2.0 Library



Runtime concept

Full access to .NET API's

Binary reuse

.NET Standard 2.0 Library

Pros

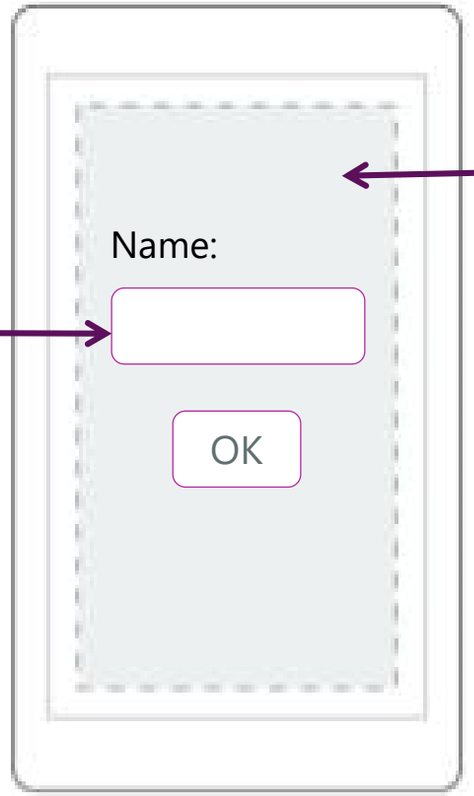
- One class library project
- Use well-known references
- Reuse DLL across platforms
- Multi-targeting option (best of both worlds)

Cons

- Not fully supported by Visual Studio for Mac yet
- Some Nuget packages don’t support .NET Standard yet

Creating the application UI

- Application UI is defined in terms of *pages* and *views*

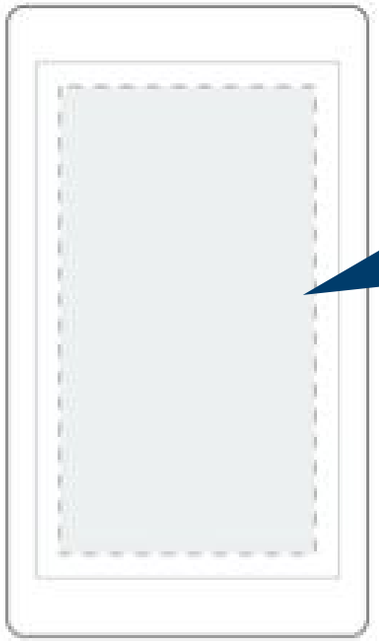


Page represents a single screen displayed in the app

Views are the UI controls the user interacts with

Pages

- Page is an abstract class used to define a single screen of content
  - derive[illegible] sp[illegible] behavior



Displays a single piece of *content* (visual thing)

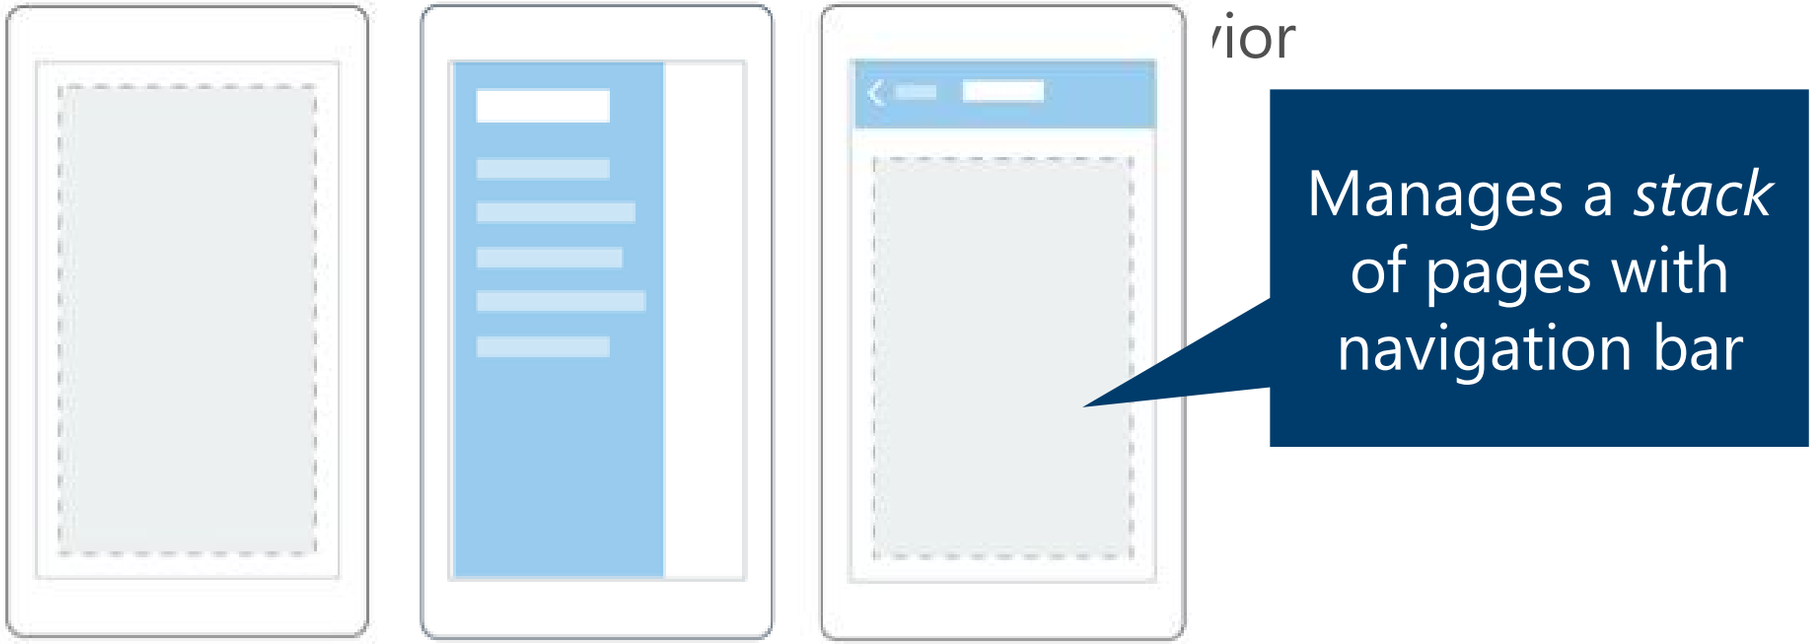
Content

Pages

- Page is an abstract class used to define a single screen of content
  - derive lizat

Pages

- Page is an abstract class used to define a single screen of content
  - derive(ior



Pages

- Page is an abstract class used to define a single screen of content

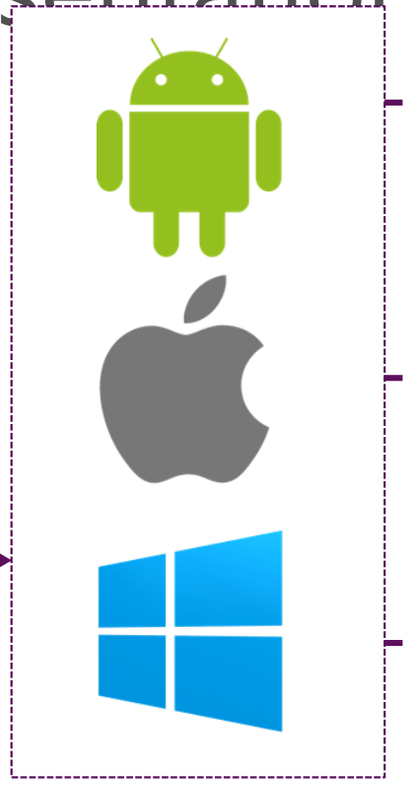
Rendering views

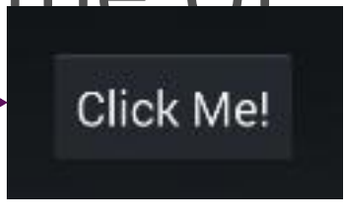
- Platform defines a *renderer* for each view that creates a native representation of the UI

UI uses a Xamarin.Forms **Button**

```
Button button = new Button {
    Text = "Click Me!"
};
```

Platform Renderer takes view and turns it into **platform-specific control**





Android.Widget.Button

UIButton

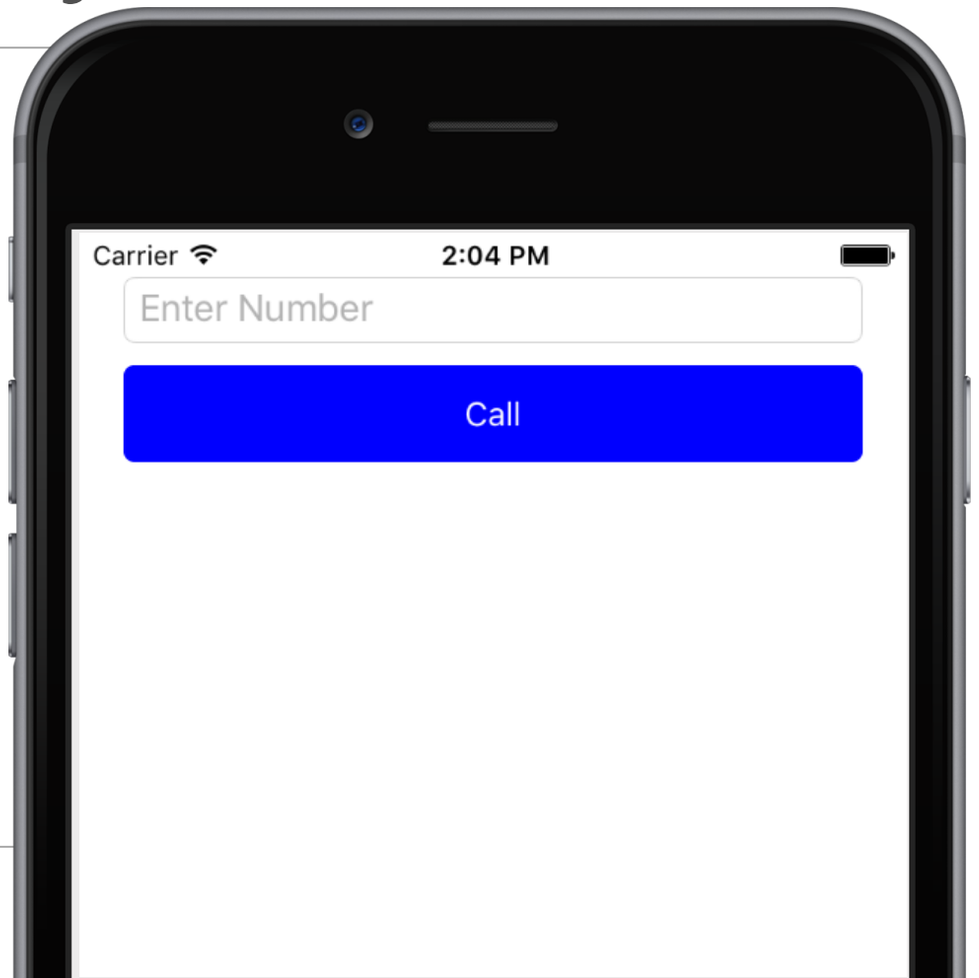
System.Windows.Button

Visual adjustments

- Views utilize **properties** to adjust visual appearance and behavior

```
Entry numEntry = new Entry {
    Placeholder = "Enter Number",
    Keyboard = Keyboard.Numeric
};

Button callButton = new Button {
    Text = "Call",
    BackgroundColor = Color.Blue,
    TextColor =  Color.White
};
```



Providing Behavior

- Controls use events to provide interaction behavior, should be very familiar model for most .NET developers

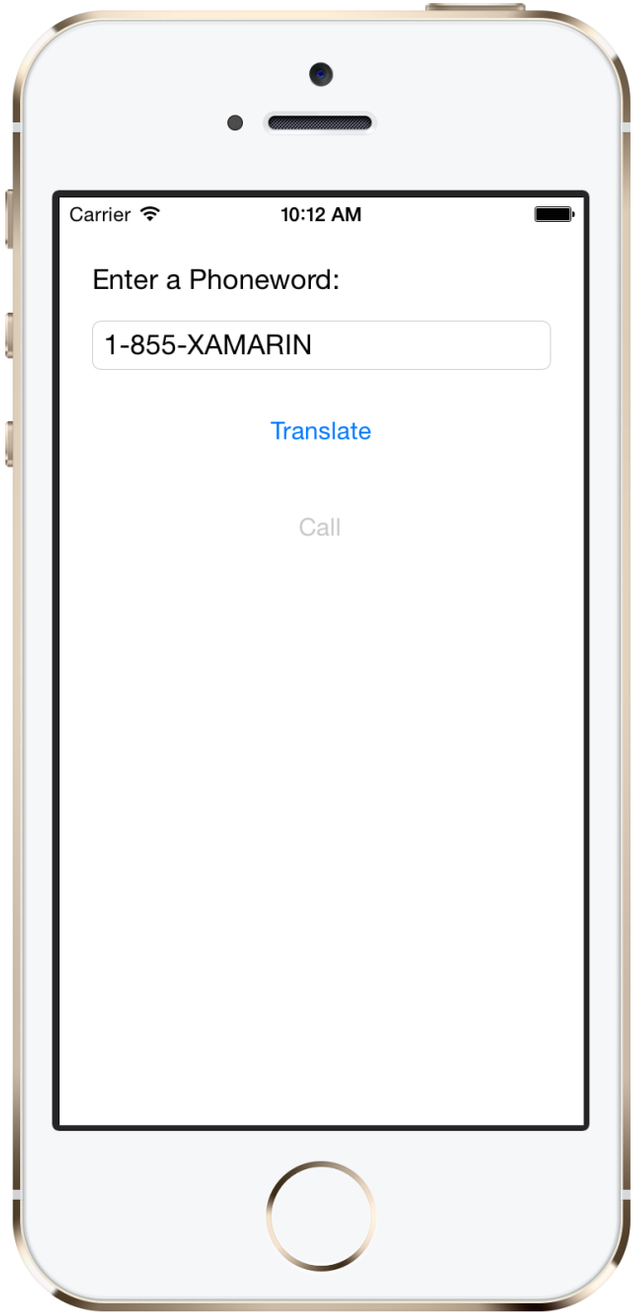
```
Entry numEntry = new Entry { ... };
numEntry.TextChanged += OnTextChanged;
...

void OnTextChanged (object sender, string newValue)
{
    ...
}
```

You can use traditional delegates, anonymous methods, or lambdas to handle events

XAML

- Our goal is to build the UI for this screen
  - Label (Enter a Phoneword:)
  - Entry (1-855-XAMARIN)
  - Button (Translate)
  - Button (Call)



Describing a screen in XAML

- XAML is used to construct object graphs, in this case a

XML based: case sensitive, open tags must be closed, etc.

Messaging center

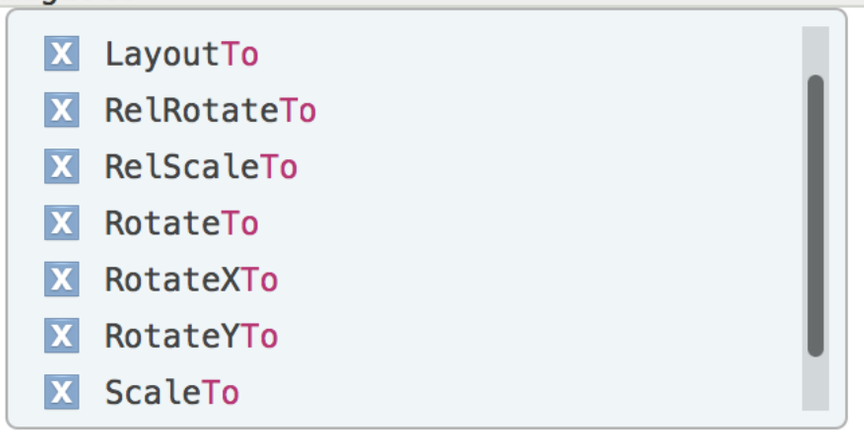
```
MessagingCenter.Send<Detail>(this, “SomeMessage");
```

```
MessagingCenter.Subscribe<Detail>(this, “SomeMessage", async (sender) =>
{
    await DoSomething();
});
```

Animations

- Cross-platform animations
- Translates to native animations as much as possible
- Async / Await API

```
ProfileImage.FadeTo (1, 1000);
ProfileImage.RotateTo (360, 1000, Easing.CubicOut);
ProfileImage.to
```



Platform tweaks

Use Device class in shared code

Xamarin.Forms.Device

- Device.Styles
  Styles for controls, e.g. labels & lists
- Device.GetNamedSize
  Font sizes
- Device.Idiom
  Tablet or phone specific code / behavior
- Device.OS
  Target platform specific code
- Device.OnPlatform()
  Target platform specific values
- Device.OpenUri()
- Device.StartTimer()
- Device.BeginInvokeOnMainThread()

XAML resources

- By default, your XAML files are included as a plain-text resource in the generated assembly which is **parsed at runtime** to generate the page

```
private void InitializeComponent()
{
    this.LoadFromXaml(typeof(MainPage));
}
```

This **Page** method looks up the embedded resource by name, parses it, and creates each object found; it returns the **root created object**

Compiling XAML

- XAML can be optionally compiled to intermediate language (IL)
  - Provides compile-time validation of your XAML files
  - Reduces the load time for pages
  - Reduces the assembly size by removing text-based **.xaml** files

Enabling XAMLC

- XAMLC (the XAML compiler) is disabled by default to ensure backwards compatibility; can be enabled through a .NET attribute

```
using Xamarin.Forms.Xaml;

[assembly: XamlCompilationAttribute(
                    XamlCompilationOptions.Compile)]
```

Can enable the compiler for all XAML files in the assembly

Enabling XAMLC

- XAMLC (the XAML compiler) is disabled by default to ensure backwards compatibility; can be enabled through a .NET attribute

```
using Xamarin.Forms.Xaml;

[XamlCompilationAttribute(XamlCompilationOptions.Compile)]
public partial class MainPage : ContentPage {
```

… or on a specific XAML-based class

What does it do?

- Attribute presence causes MSBuild command to be run which parses the XAML and generates **`InitializeComponent`** to create the page in code

```
private void InitializeComponent()
{
    Label label = new Label();
    StackLayout stackLayout = new StackLayout();
    stackLayout.SetValue(VisualElement.BackgroundColorProperty,
         new ColorTypeConverter().ConvertFrom("Red"));
    stackLayout.SetValue(Layout.PaddingProperty,
         new ThicknessTypeConverter().ConvertFrom("10"));
    stackLayout.SetValue(StackLayout.SpacingProperty, 5);
    label.SetValue(Label.TextProperty, "Hello, Forms");
    stackLayout.Children.Add(label);
    ...
    this.Content = stackLayout;
}
```

Disabling XAMLC

- Attribute also lets you disable XAMLC for a specific class

```
using Xamarin.Forms.Xaml;

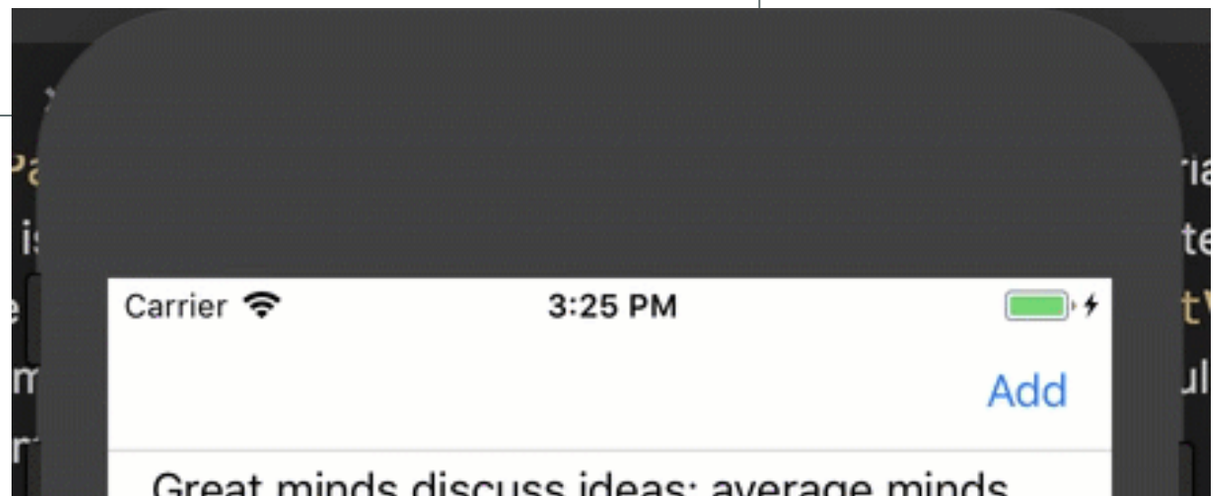
[XamlCompilationAttribute(XamlCompilationOptions.Skip)]
public partial class DetailsPage : ContentPage {
```

Specify **Skip** to turn off compiler for this specific page; goes back to using **`LoadFromXaml`**

Using the toolbar

- You can interact with some nice platform features, such as:

```
<?xml version="1.0" encoding="UTF-8" ?>
<ContentPage … >
      <ContentPage.ToolbarItems>
            <ToolbarItem Text="Add" Clicked="AddQuote" />
      </ContentPage.ToolbarItems>
</ContentPage>
```



Context actions

- You can interact with some nice platform features, such as:

```
<TextCell ...>
      <TextCell.ContextActions>
            <MenuItem Clicked="OnDelete”
                      CommandParameter="{Binding .}”
                      Text="Delete”
                      IsDestructive="True" />
      </TextCell.ContextActions>
</TextCell>
```
